

GEOLOGICAL NOTES.

[The bearings refer to the magnetic meridian.]

- 61-62. The section across the Huronian belt on the E. River, shows a variety of dark grey, hornblende and quartzite schists, dark green massive and schistose diorites, crystalline reddish diorites, grey and greenish fine grained quartzite mica-schists, and fine grained hard grey impure gneisses. The general strike is south-easterly.
63. Dark green diorite and dark-quartzite, with a hill to the northward consisting partly of grey and partly of red fine grained granite.
- 64-65. The Huronian rocks exposed along the Black River consist of dark greyish green and reddish diorites (some of them porphyritic), red and grey granites, conglomerates, fine grained mica-schists, diorites, silicified, argillaceous, hornblende, chloritic, felspathic and epidotic schists and impure gneisses, similar to those on the E. River. The general strike is W. & N.W.
66. Greyish and reddish gneisses, occasionally interstratified with bands of dark hornblende schist and very light grey gneiss.
67. Five grained dark green hornblende schists, having the same strike as the adjacent gneiss.
- 68-69. Hornblende, silicified and chloritic schists. Strike, N. & N.W.
70. Hornblende schists with veins of quartz and feldspar, and veins of calcopier and quartz containing yellow and vitreous sulphides of copper, iron pyrites, blende, galena and wolframite.
71. Murchison Island and the extremity of Cape George consist of argillaceous, conglomerates, sandstones, calcareous limestones, etc., belonging to the Cambrian (Canadian) series.
72. Light red granite of medium texture. It is found on the east by hornblende schist.
73. Soft grey slate holding layers and joints of calcopier and patches of reddish granite.
74. Greyish slaty diorite with thick beds of reddish siliceous and brittle hornblende interstratified with grey siliceous layers.
75. Dark coloured hornblende mica-schist.
76. Massive green dioritic schist.
77. Massive and slaty diorites and grey calcareous schists with traces of copper.
78. Massive red and grey granite of medium texture and good workable character.
79. Soft grey granite of medium texture. It is found on the east by hornblende schist.
80. Gloomy green mica and hornblende schists, greenish-grey slaty quartzite, massive crystalline green diorite, dioritic schist, soft calcareous grey mica-schist and brittle reddish yellow siliceous or cherty schists. At the N. W. extremity of Cape George a line patch of thin-bedded red and grey sandstone rests unconformably upon these rocks.
81. Small patches of red slaty volcanic breccia resting upon gneiss.
82. Massive, even and rather finely grained pinkish-grey granite.
83. Green chloritic, grey felsitic and fine grained mica-schists, with diorites and gneisses.
84. Red and grey syenitic granites.
85. Chloritic and dioritic schists with masses of fine-grained granite and syenite.
86. Fine grained massive soft greenish-grey calcareous schist.
87. Green hornblende schist with pebbles, chloritic and dioritic schists.
88. Narrow bands of dark green mica-schist and mica-schist, and mica-schist, hornblende, dioritic, siliceous and felsitic schists.
89. Dark grey siliceous slate and dark green felsitic hornblende-schist, with greyish mica-schist towards the gneiss on either side.
90. Siliceous felsitic and mica-schist, with quartzites and diorites.
91. Dark hornblende and mica-schist with layers of light-coloured granite running with the strike.
92. Beds of lignite, from 1 to 6 feet in thickness, in leather clay. (See p. 4c Report for 1877-78.)
93. Gypsum in the N. W. bank begins at 8 miles, and is not seen in the S. E. bank at 16 miles below this point. It is about 10 feet thick, and is associated with earthy greyish and buff-coloured magnesian limestone and calcareous shale of Devonian age.
94. Siliceous hornblende schist.
95. Red and reddish grey syenitic granite with patches of grey amygdaloid, containing calcopier, fluoropier and apatite.
96. Rather dark-coloured hornblende schist with a general westerly strike.
97. Lead and copper ore discovered by Mr. Jones in veins in Huronian rocks.
98. Huronian rocks striking north of and, probably near their junction with the Laurentian.

SCALE OF COLOURS

LAURENTIAN. GRANITE. HURONIAN.

GEOLOGICAL NOTES.

[The Bearings refer to the Magnetic Meridian.]

1. Felsite, generally ribboned purple and green: some parts grey and siliceous. The general strike is parallel to the course of the East Branch of the Moose River. At the outlet of White Beaver Lake it is associated with a beautiful blue-coloured brecciated chert.
2. Quartzites, mostly light grey, and in places approaching the character of sandstone, white to where they are full of pebbles. Some portions are brownish, some greenish, and others dark grey. At White Beaver Lake the surface of the beds occasionally shows ripple-marks.
3. Massive crystalline greenish grey diorite, mostly of dark shades.
4. Dark greenish grey argillaceous mica-schist, pebbles mostly of red syenitic granite, with some of white quartz and green schist.
5. Dark hornblende schist, full of veins and masses of grey pyroxenite; all cut by veins of siliceous quartz.
6. Great alternating masses of grey quartzite and dark-coloured diorite, both of which are frequently of a coarse conglomerate character, the pebbles consisting of syenitic granite, quartzite, and various slates of the Huronian series, mostly rounded and crowded together in great bands. These massive beds are interstratified with sandstone or shale. The dip is from E. to E. N. E., at an angle of 30°.
7. Belt of quartzite with copper pyrites and crystalline specular iron. Dip N. 70° W.
8. Red and grey syenitic granite, mostly coarse in texture.
9. Dark hornblende and siliceous schist.
10. Greenish grey diorite mica-schist with smooth rounded pebbles of syenitic granite.
11. Bedded reddish quartzite, mostly fine grained and interstratified with greenish siliceous schist.
12. Greenish and grey argillaceous and siliceous slates.
13. Dark green serpentine with calcopier and calcopier, and containing chromite.
14. Massive light grey felsitic volcanic ash with dark and light specks.
15. Soft greenish grey magnesian rock, rarely stratified and thickly interstratified in all directions by calcopier slings.
16. Hornblende and dioritic schists dipping south-eastward at high angles.
17. Greenish grey quartzite, partly massive and partly schistose. They hold transparent grains of quartz.
18. Dykes of crystalline dark greenish grey diorite.
19. Dark grey hornblende schist. Strike, S. 75° E.; angle northward, 65°.
20. Grey massive mica-schist, chloritic and greenish grey siliceous and dolomitic schist, with pebbly surfaces and cut by quartz veins.
21. Siliceous grey slate, running W. N. W.
22. Fine grained greenish grey quartzite, followed, half a mile to the N., by bluish grey clay-slate, and further N. by more quartzite.
23. Stratified greenish grey crystalline somewhat schistose diorite, cut by irregular quartz and calcopier veins. The dip is northward at an angle of 80°.
24. Grey siliceous slate, grey felsitic and dark bluish grey clay-slate. Dip N., angle 60° to 70°.
25. Green and grey massive chloritic and talcoid schists. Dip N., angle 60°. Cut by a great dyke running N. and S.
26. Massive grey semi-crystalline diorite, holding grains of specular iron, and cut by small veins of blue-quartz.
- 27-28. Massive and slaty greenish grey diorite.
29. Hard greenish grey slaty diorite, cut by a great dyke, running N. and S.
30. Soft greenish grey calcareous talcoid schist. Strike N. 55° W.
31. Grey volcanic ash, followed by greyish green chloritic and dioritic schists. Dip E. N. E.
32. Dark greenish grey hornblende schist, with some chloritic schist. Strike, N. 55° to N. 70° W.
- 33-34. Laurentian gneiss begins at the foot of Davis' Rapids and is found all along the river to the foot of the Long Portage, which appears to mark the southern boundary of the Huronian area.
35. Soft dark mica-schist.
36. Soft yellowish and reddish grey porous limestone.
37. Calcareous-sandstone, micaceous, with green spots.
38. Dark grey argillaceous schist, cut by dykes of dark, compact diorite.
39. Greenish calcareous mica-schist and hornblende schist.
- 40-41. Tender grey mica-schist with many partings.
42. Fine grained massive grey calcareous diorite.
43. Grey slightly calcareous argillaceous schist, with thin partings of calcopier in the joints.
44. Unstratified greenish grey diorite with disseminated grains of iron pyrites, and in some places holding vesicles filled with calcopier and white quartz.
45. Dark green argillaceous weathering dull white, strongly magnetic and containing grains of chromite iron.
46. Micaceous, hornblende, chloritic and dioritic schists, quartzites and diorites.
47. Impure, hard, close-grained grey limestone.
48. Closely stratified dark greenish grey dioritic schist.
49. Hill 600 feet high, of fine-grained grey quartzite.
50. Conglomerates with partings, and slaty matrix with rounded pebbles of syenitic diorite, felsite and white quartz.
51. Hornblende and mica-schist.
52. Micaceous hornblende, chloritic and steatitic schists, associated with massive steatite, quartzite, magnetic pyrites, iron ore and mica.
53. Very light grey and bluish greenish grey schists associated with dark syenitic gneiss holding iron and white quartz.
54. Greenish green hornblende schist conformable with the gneiss to the east of it.
55. Slaty diorites, with layers of ribboned quartzite, jasper and magnetic iron.
56. Bed of greyish felsite with copper and iron pyrites just below the 7th portage from Lake Temiscaming.
57. Soft greenish grey felsitic rock.
58. Hard dark grey felsitic mica-schist.
59. Boulder conglomerates overlaid by light grey limestone, all belonging to the Niagara formation. (See GEOLOGY OF CANADA, p. 334.)
60. Reddish syenitic gneiss composed of red orthoclase and white quartz with a small quantity of green hornblende.

This area appears to be occupied by massive crystalline dark green diorites, but its central portion has not yet been explored. See Geological Survey Reports 1878, pages 108, 125 and 185; 1876, pages 502 and 512, and 1877, page 57 C.
